

Kotlin List – Examples

Kotlin List

Kotlin List is one of the three Collections (List, Set, Map). List is a collection of elements whose position in the collection is preserved, whereas in Set or Map, there is no fixed position/index for an element. Hence, elements in a list can be accessed using index.

List is immutable, so, you cannot update individual elements of list or add items to the original list.

But if you want to create a list that could be mutable, Kotlin provides `MutableList<T>` class to define a mutable list.

In this tutorial, we shall learn with examples on how to access and modify items in a list, and how to convert it to other Collection types.

Kotlin List – Initialize

To initialize Kotlin List, use `mutableListOf(vararg items : T)` method. The method returns a `MutableList<T>`.

In the following example,

```
var listA = listOf<String>("Example", "Program", "Tutorial")
var listB = mutableListOf("Example", "Program", "Tutorial")
```

`listA` is an immutable list of type `List<String>`, since each of the element in the list is of type `String`.

`listB` is a mutable list of type `MutableList<String>`.

Kotlin List – Get Element

`List.get()` is used to read elements of a list using index.

You can also use array style accessing of elements using square brackets `[]`.

```

fun main(args: Array<String>) {
    //initialize list
    var listA = listOf<String>("Example", "Program", "Tutorial")

    //accessing elements using square brackets
    println(listA[0])

    //accessing elements using get()
    println(listA.get(2))
}

```

Output

```

Example
Tutorial

```

In the above example, we have used square brackets to read element present at index `0` and used `get()` method to read element at index `2`.

Kotlin – Add Element to List

Since we cannot modify a `List<T>`, we shall learn how to add an element to a mutable list, `MutableList<T>`.

To append item to the list, use `MutableList.add(item : T)` method.

Kotlin Program – example.kt

```

fun main(args: Array<String>) {
    //initialize a mutable list
    var listA = mutableListOf("Example", "Program", "Tutorial")

    //add item to the list
    listA.add("Sample")

    //print the list
    println(listA)
}

```

Output

```
[Example, Program, Tutorial, Sample]
```

The item is added to the end of list.

Kotlin – Check if List Contains an Element

To check if an element is present in the list, use `List.contains()` method on the list. `contains()` return `true` if the element is present, else `false` is returned.

Kotlin Program – example.kt

```
fun main(args: Array<String>) {
    //create a list
    var listA = listOf<String>("Example", "Program", "Tutorial")

    //check if the list contains element "Program"
    val b = listA.contains("Program")

    //based on the result of contains(), print a message
    if(b){
        print("Program is present in the list.")
    } else{
        print("Program is not present in the list.")
    }
}
```

Output

```
Program is present in the list.
```

As the element is present in the list, `b` is set to `true` and hence the print statement with the string `"Program is present in the list."` is executed.

Kotlin – Find Element in List

You can use `List.find()` function to find the first element that satisfies a predicate provided to the `find()` method. Element of the list can be accessed using `it`. Observe the following example program and output, and you shall follow what we are talking about this `find()` function.

In the following example, we find the first element that contains string `"am"`. `find()` method returns the first element that satisfies the condition posed by predicate.

Kotlin Program – example.kt

```
fun main(args: Array<String>) {
    //initialize the list
    var listA = listOf<String>("Example", "Program", "Tutorial")

    //find the element
    val b = listA.find { it.contains("am") }

    //print the element
    print(b)
}
```

Output

```
Example
```

Kotlin – Filter Elements of List

List.filter() function can be used to filter elements of list based on a predicate. **it** in the predicate represents each element.

In the following example, we filter a list for the elements containing “am”. filter method returns new list with items filtered based on the predicate.

Kotlin Program – example.kt

```
fun main(args: Array<String>) {
    //initialize a list
    var listA = listOf<String>("Example", "Program", "Tutorial")

    //filter the list
    val b = listA.filter { it.contains("am") }

    //print the filtered list
    print(b)
}
```

Output

```
[Example, Program]
```

The filtered output contains elements that satisfy the predicate we passed to filter() function.

Kotlin List – For Loop

To iterate over all the elements of a list, for loop can be used. Following is an example to print all elements of a list using for loop.

Kotlin Program – example.kt

```
fun main(args: Array<String>) {
    //initialize a list
    var listB = listOf<String>("Example", "Program", "Tutorial")

    //for loop on list
    for(item in listB){
        println(item)
    }
}
```

Output

```
Example  
Program  
Tutorial
```

Conclusion

In this [Kotlin Tutorial](#) – **Kotlin List**, we have learnt to initialize a List with items, access them, filter them based on a predicate, find an element based on a predicate, etc.
